DEVICE TEST

1, Explain behaviour of hub device

A hub is a layer 1 device used to connect multiple devices in a Lan

- * Hub receives data from one device, it send's data to all other ports, It does not check the destination MAC addresses
- * All connected device Receive the data but only one indeded device processes it
- * multiple device transmit at the same time, collisions can occur

2, Explain behaviour of switch device

A Switch Receives a data frame, learns the Source MAC address, check the destination MAC address and forward's the frame only to the correct destination Port, Reducing network traffic and collisions

3, Explain behaviour of router device

A router checks the destination IP address of a packet and select the best route using its routing table.

It forwards the packet through the appropriate interface toward the destination network

If no suitable route is available, the route drops the packet.
